

SELF ORTHOGONAL DECODING CIRCUIT AND

SELF ORTHOGONAL DECODING METHOD

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates generally to a self orthogonal decoding circuit and a self orthogonal decoding method. More particularly, the invention relates to a decoding method and a decoding circuit for a self orthogonal code as
10 convolution code which is quite simple and easy to apply to systems.

Description of the Related Art

Self orthogonal code has been known as being quite simple and easy to apply for systems and has been widely applied in
15 the field of satellite communication, optical communication or communication by a wire cable. However, in comparison with Viterbi decoding as most-probable decoding of the convolution code, the conventional self orthogonal code is lower in error correction performance.

20 A construction of the conventional decoder for self orthogonal code is illustrated in Fig. 25. In Fig. 25, there is illustrated a construction of the case of self orthogonal code in a coding ratio of 1/2. In this case, code generating polynomial expression is assumed to be:

$$G1 = 1 + x^2 + x^5 + x^6 \quad \dots (1)$$

number of orthogonal is assumed to be four. Theoretical background of the self orthogonal code and detail of realizing method of the conventional decoder has been disclosed in Hideki Imai, "Coding Theory", The Institute of Electronics, Information and Communication Engineers, March, 1990, pp 274 to 278.

In the self orthogonal code of coding ratio 1/2, check series of the same proportion to information series is added in the encoder to generate a transmission series, in which information series and check series are arranged alternately. The transmission series is output to a line. Then a reception series Y added an error to the transmission series is input to the decoder.

The conventional self orthogonal decoder is constructed with a code synchronization and serial/parallel converter circuit 7, a syndrome series generation circuit 8, an error value generation circuit 10 and an error correcting portion 9.

The reception series input to the decoder is input to the code synchronization and serial/parallel converter circuit 7. The code synchronization and serial/parallel converter circuit 7 establishes synchronization of the code and performs serial/parallel conversion of the reception series Y into the information series I and the check series P to output to the

096495-09601
T09260-56749660

syndrome series generation circuit 8.

Code synchronization is performed on the basis of an error count value EC input from the error value generation circuit 10. For example, when the error count value EC is greater than or equal to a threshold value, out of code synchronization is judged to vary a phase of the parallel signal to be output to the syndrome series generation circuit 8. The syndrome series generation circuit 8 generates a syndrome series S on the basis of the information series I and the check series P input from the code synchronization and serial/parallel converter circuit 7.

A construction of the syndrome series generation circuit 8 is shown in Fig. 26. In Fig. 26, the syndrome series generation circuit 8 is constructed with first to sixth order information series registers 81-1 to 81-6 and an exclusive OR circuit 82.

The information series I is input to the first order information series register 81 and then shifted in sequential order from the second to sixth information series shift registers 81-2 to 81-6 at every occurrence of clock. The information series I thus delayed by the first to sixth information series shift registers 81-1 to 81-6 to be output to the error correcting portion 9 as delayed information series ID.

Number of stages of the information series registers corresponding to number of orders of the generation polynomial expression. The input information series I corresponds to (0)th

0964195-092601
109260-06TH960

order of the generation polynomial expression. Data corresponding to the order of the generation polynomial expression having coefficient other than 0 and the check series P are input to the exclusive OR circuit 82.

5 In the shown example, the generation polynomial expression has coefficients other than 0 in zeroth, second, fifth and sixth order. Therefore, information series I, outputs of the second, fifth and sixth information series registers and the check series P are input to the exclusive OR circuit 82.

10 The exclusive OR circuit 82 takes an exclusive OR of the input signal to output it to the error value generation circuit 10 as the syndrome series S.

 The error value generation circuit 10 leads an error value on the basis of the syndrome series S input from the syndrome series generation circuit 8. A construction of the error value generation circuit 10 is illustrated in Fig. 27. In Fig. 27, the error value generation circuit 10 is constructed with zeroth to fifth syndrome registers 101-0 to 101-5, a majority decision judgment circuit 103, an error detection counter 104 and syndrome
15 correcting exclusive OR circuit 101-1 to 102-3. Number of order of the syndrome registers corresponds to number of order of the generation polynomial expression.

 The input syndrome series S corresponds to the highest order (sixth order) of the generation polynomial expression.
25 Data corresponding to number of order of the expression

09964195-092601

polynomial expression having the coefficient other than zero, is input to the majority decision judgment circuit 103. Assuming the number of orthogonal is J, the judgment threshold value A of the majority decision judgment circuit 103 becomes:

5

$$A = \lfloor J/2 \rfloor \quad \dots\dots (2)$$

The majority decision judgment circuit 103 makes judgment that error is caused when number of input signals having value "1" is greater than or equal to A, "1" is output as an error value E. When the majority decision judgment circuit 103 outputs "0" as the error value E with judgment that error is not caused when number of input signals having a value "1" is less than the judgment threshold value A.

15 Since the generation polynomial expression in the shown example has coefficients other than zero at zeroth, second, fifth and sixth order, outputs of the zeroth, second and fifth syndrome registers 101-0, 101-2 and 101-5 and the syndrome series S are input to the majority decision judgment circuit 103.

20 Accordingly, the majority decision judgment circuit 103 has four input signals. The majority decision judgment circuit 103 makes judgment as error being caused when number of the input signals having values "1" is greater than or equal to three to output "1" as the error value E.

09064195-092604
109260-5674960

The syndrome series S is shifted from higher order syndrome register to lower order syndrome register at every occurrence of clock. It has been known that when error is detected in the majority decision judgment circuit 103 influence of the error is eliminated from the syndrome series S to achieve enhancement of error correction performance. In order to eliminate influence of error from the syndrome series S, the signal input to the majority decision judgment circuit 103 is inverted the value when the error is detected and then input to the lower order syndrome register.

More particularly, inversion of the values is performed by the syndrome correcting exclusive OR circuit 102-1 to 102-3. The syndrome correcting exclusive OR circuits 102-1 to 102-3 take the syndrome series S and the outputs of the fifth and second syndrome registers 101-5 and 101-2 as first input, and take the error value E as second input. The syndrome correcting exclusive OR circuit 102-1 to 102-3 takes an exclusive OR of the first input and the second input to output the results of exclusive OR operation to the fifth, fourth and first syndrome registers 101-5, 101-4 and 101-1.

The error detection counter 104 takes an error value E as input and counts number of error detected within a given period. The counter error count value EC is output to the code synchronization and serial/parallel converter circuit 7. The error correcting portion 9 makes correction of the delayed

09964195-092601

information series ID input from the error value generation circuit 10 on the basis of the error value E input from the syndrome series generation circuit 8 to output as a corrected information series IC.

5 While the foregoing conventional self orthogonal decoding circuit is simple in decoding and easy to apply for systems, it holds shortcoming in lower error correction performance in comparison with Viterbi decoding as most-probable decoding of the convolution code.

10 SUMMARY OF THE INVENTION

 The present invention has been worked out in view of the problem set forth above. It is therefore an object of the present invention to provide a self orthogonal decoding circuit and a method thereof, which can be realized with simple circuit
15 construction and can significantly improve error correction performance.

 According to the first aspect of the present invention, a self orthogonal decoding circuit performing decoding for self orthogonal code repeats decoding for the self orthogonal code
20 for a plurality of times.

 According to the second aspect of the invention, a self orthogonal decoding circuit performing decoding for self orthogonal code on the basis of syndrome bit determined only by an error in a reception series which is generated by adding
25 error to a transmission series which is in turn generated by

0906495-092601

parallel/serial conversion with adding a check series to an information series, comprising:

a plurality of stages of decoding circuit for repeating decoding for the self orthogonal code for a plurality of times;

5 and

check series register provided for each of decoding circuit except for the decoding circuit at a final stage among the plurality of stages of decoding circuits and for inputting the check series to next stage of decoding circuit with delay.

10

According to the third aspect of the present invention, a self orthogonal decoding method for performing decoding for self orthogonal code repeating decoding for the self orthogonal code for a plurality of times.

According to the fourth aspect of the present invention, 15 a self orthogonal decoding method performing decoding for self orthogonal code on the basis of syndrome bit determined only by an error in a reception series which is generated by adding error to a transmission series which is in turn generated by parallel/serial conversion with adding a check series to an information series, comprises a step of:

20

in each of a plurality of stages of decoding circuit for repeating decoding for the self orthogonal code for a plurality of times, the check series being input to next stage of decoding circuit with a delay except for the decoding circuit at the

25 final stage.

09364195-092604

Namely, in the self orthogonal decoding circuit according to the present invention, error correction performance can be improved by repeating decoding for the self orthogonal code for a plurality of times.

5 More particularly, in the self orthogonal decoding circuit according to the present invention, by employing a construction for inputting the check series to the decoding circuit in the next stage with delay by the check series register to enable decoding for a plurality of times.

10 On the other hand, in the plurality of stages of decoding circuits, a threshold value judgment threshold value for making judgment as error in first decoding is set large to make correction only for high probability of error being corrected, and the threshold value judgment threshold value being gradually reduced
15 as repeated decoding for the self orthogonal code, for making correction for lower probability of error. This reduces occurrence of erroneous correction to significantly improve error correction performance.

In the preferred construction, the self orthogonal
20 decoding circuit may comprise means for performing code synchronization judgment by counting number of errors as being judged as error and performing code synchronization on the basis of counted error number.

Also, the self orthogonal decoding circuit may comprise
25 code synchronization dedicated threshold value judgment circuit

09064195-092601

provided separately from the circuit for making judgment of the error and dedicated for code synchronization and making judgment whether error is caused or not on the basis of threshold value judgment threshold value optimized for code synchronization and the threshold value of the code synchronization dedicated threshold value judgment circuit to be lower than the threshold value judgment threshold value. In such case, the self orthogonal decoding circuit may comprise a syndrome register which shifts the syndrome bit provided for code synchronization to output to the code synchronization dedicated threshold value judgment circuit, so as not to perform correction on the basis of the result of error judgment of the code synchronization dedicated threshold value judgment circuit for the syndrome register.

15 In the alternative, each decoding circuit in the plurality stages comprises:

syndrome generation means for generating the syndrome bit;

error value generation means for leading an error value by making judgment of error of the syndrome bit generated by the syndrome generation means on the basis of the threshold value judgment threshold value;

error correcting means for correcting error of the syndrome bit on the basis of the error value generated by the error value generation means; and

09964195-092601

error detection counter for counting the error number on the basis of the error value generated by the error value generation means.

5 A system including an information source generating an information series, an encoder for converting the information series into a code series, and a communication path for transmitting the code series, may perform decoding for the self orthogonal code is repeated for a plurality of times. In such case, the communication path is constructed with a wired cable.
10 The wired cable may be an optical cable. In the alternative, the communication path may be a transmission path in radio communication.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be understood more fully from
15 the detailed description given hereinafter and from the accompanying drawings of the preferred embodiment of the present invention, which, however, should not be taken to be limitative to the invention, but are for explanation and understanding only.

DESCRIPTION OF THE PREFERRED EMBODIMENT

The present invention will be discussed hereinafter in detail in terms of the preferred embodiment of a self orthogonal decoding circuit according to the present invention with reference to the accompanying drawings. In the following description, numerous specific details are set forth in order to provide a thorough understanding of the present invention. It will be obvious, however, to those skilled in the art that the present invention may be practiced without these specific details. In other instance, well-known structure are not shown in detail in order to avoid unnecessary obscurity of the present invention.

Fig. 1 is a block diagram showing a construction of the

0996495-092601

preferred embodiment of a self orthogonal decoding circuit according to the present invention. In Fig. 1, the shown embodiment of self orthogonal decoding circuit according to the present invention is constructed with a code synchronization
5 and serial/parallel converter circuit 1, a first stage decoding circuit 2 and a second decoding circuit 3.

Here, coding ratio is assumed to be $K/(K+1)$, number of orthogonal is J , and first to (K) th generation polynomial expressions G_1 to G_K are as follows.

10

$$G_1 = x^{d_{1,1}} + x^{d_{1,2}} + \cdot \cdot \cdot + x^{d_{1,J}}$$

$$G_2 = x^{d_{2,1}} + x^{d_{2,2}} + \cdot \cdot \cdot + x^{d_{2,J}}$$

.

15

.

.

$$G_K = x^{d_{K,1}} + x^{d_{K,2}} + \cdot \cdot \cdot + x^{d_{K,J}}$$

..... (3)

20

$$d_{1,1} < d_{1,2} < \cdot \cdot \cdot < d_{1,J}$$

$$d_{2,1} < d_{2,2} < \cdot \cdot \cdot < d_{2,J}$$

.

.

.

09964195-09601
T09260"56T4960

$$d_{K,1} < d_{K,2} < \dots < d_{K,J}$$

The number of orthogonal J is number of orders having coefficients,
in which the generation polynomial expression is other than
5 zero.

In the self orthogonal code of coding ratio $K/(K+1)$, check
series is added to the first to (K)th information series in
not shown encoder for generating a transmission series through
parallel/series conversion of (K+1) in number of parallel
10 signals. The transmission series is output to a line. A
reception series Y generated by adding an error to the
transmission series is input to a decoding circuit. It should
be noted that the self orthogonal code has been disclosed in
Hideki Imai, "Coding Theory", The Institute of Electronics.
15 Information and Communication Engineers, March, 1990, pp 274
to 278.

The reception series Y input to the decoding circuit is
input to the code synchronization and serial/parallel converter
circuit 1. The code synchronization and serial/parallel
20 converter circuit 1 establishes code synchronization and
performs serial/parallel conversion for the reception series
Y to generate the information series I1 to IK and the check
series to output to the first stage decoding circuit 2.

Code synchronization is performed on the basis of the
25 error count value EC input from the first stage decoding circuit

09564195-092601

2. For example, when the error count value EC is greater than or equal to the threshold value, judgment is made that the code synchronization is broken, the phase of the parallel signal output to the first stage decoding circuit 2 is varied.

5 The first stage decoding circuit 2 takes the information series I1 to IK and the check series P as inputs for performing error correction on the basis of the information series I1 to IK and the check series P for outputting first stage corrected first to (K)th information series I1_C1 to IK_C1 and a delayed
10 check series PD to the second decoding circuit 3. The second decoding circuit 3 performs error correction for the first stage corrected first to (K)th information series I1_C1 to IK_C1 in which number of error has been decreased by the first stage decoding circuit 2 for further decreasing number
15 of error.

Fig. 2 is a block diagram showing a construction of the first stage decoding circuit 2 shown in Fig. 1. In Fig. 2, the first stage decoding circuit 2 is constructed with a syndrome series generation circuit 21, an error value generation circuit
20 22, an error correction circuit 23, an error detection counter 24 and an check series register 25.

The syndrome series generation circuit 21 generates a syndrome series S1 on the basis of the first to (K)th information series I1 to IK and the check series P input from the code
25 synchronization and serial/parallel converter circuit 1. The

0906495-092601
T09260-554960

error value generation circuit 22 derives an error value on the basis of the syndrome series S1 input from the syndrome series generation circuit 21.

The error detection counter 24 takes error values E1_1 to EK_1 as input from the error value generation circuit 22 for counting number of error. The error count value EC thus counted is output to the code synchronization and serial/parallel converter circuit 1.

The error correction circuit 23 corrects delayed information series I1_D1 to IK_D1 input from the syndrome series generation circuit 21 on the basis of the error values E1_1 to EK_1 input from the error value generation circuit 22 to output first to (K)th first stage corrected information series I1_C1 to IK_C1 to the second decoding circuit 3.

The check series register 25 is used for transferring the check series P to the second decoding circuit 3. Assuming that a maximum value at maximum order $d_{1,j}$ to $d_{k,j}$ of the first to (K)th generation polynomial expressions G_1 to G_k , is d_{max} , the check series register 25 is constructed with d_{max} in number of shift registers. The check series P is input to the check series register 25 and is shifted at every occurrence of clock. The check series P delayed for d_{max} clock is output to the second decoding circuit 3 as the delayed check series PD.

Fig. 3 is a block diagram showing a construction of the syndrome series generation circuit 21 shown in Fig. 2. In Fig.

09064195-092601

3, the syndrome series generation circuit 21 is constructed with first to (K)th information series registers 211-1 to 211-K, first to (K)th information series exclusive OR circuits 212-1 to 212-K and syndrome series generating exclusive OR circuit 5 213.

Assuming that the maximum value at maximum order $d_{1,j}$ to $d_{k,j}$ of the first to (K)th generation polynomial expressions G_1 to G_k , is d_{max} , each of the first to (K)th information series registers 211-1 to 211-K is constructed with d_{max} in number of 10 the shift registers. The first to (K)th information series I1 to IK are input to the first to (K)th information series registers 211-1 to 211-K and shifted at every occurrence of the clock. The first to (K)th information series I1 to IK delayed for d_{max} is output to the error correction circuit 23 as first to (K)th 15 delayed information series I1_D1 to IK_D1.

The d_{max} in number of shift registers in the first to (K)th information series registers 211-1 to 211-K corresponds to number of orders of the first to (K)th generation polynomial expressions. Particularly, the output of the first stage 20 register receiving input of the first to (K)th information series I1 to IK correspond to the first order of the generation polynomial expression. The output of the (d_{max})th shift register corresponds to the (d_{max})th order of the polynomial expression. The first to (K)th information series I1 to IK correspond to 25 zeroth order of the polynomial expression.

096495 09260" 56749660

The signals corresponding to order number of the generation polynomial expression having coefficients other than zero are input to first to (K)th information series exclusive OR circuits 212-1 to 212-K. For example, the first generation polynomial expression G_1 has coefficients other than zero at J in number of order number of $d_{1,1}$ to $d_{1,J}$. Therefore, the outputs of the $(d_{1,1})$ th to $(d_{1,J})$ th shift registers in the first information series registers 211-1 are input to the first information series exclusive OR circuit 212-1.

The first to (K)th information series exclusive OR circuits 212-1 to 212-K take exclusive OR of J in number of input signals to output the result of exclusive OR operation to the syndrome series generating exclusive OR circuit 213. The syndrome series generating exclusive OR circuit 213 takes an exclusive OR of the outputs of the first to (K)th information series exclusive OR circuits 212-1 to 212-K and the check series P to output the result of exclusive OR operation to the error value generation circuit 22 as the syndrome series S1.

Fig. 4 is a block diagram showing a construction of the error value generation circuit 22 of Fig. 2. In Fig. 4, the error value generation circuit 22 is constructed with a syndrome register 221 and first to (K)th threshold value judgment circuits 222-1 to 222-K.

The syndrome register 221 is constructed with d_{\max} in number of shift registers. The syndrome series S1 is input to the

09064195-092601
F09260-56T4960

syndrome register 221 and shifted at every occurrence of clock.
The d_{\max} in number of the shift registers in the syndrome register
221 correspond to order number of the generation polynomial
expression. Particularly, the output of the first stage
5 register input the syndrome series S1 corresponds to $(d_{\max}-1)$
of generation polynomial expression. The output of the (d_{\max}) th
shift register corresponds to zeroth polynomial expression.
The syndrome series S1 corresponds to (d_{\max}) th generation
polynomial expression.

10 The signals corresponding to order number of the
generation polynomial expression having coefficients other than
zero, are out to the threshold value generation circuit. For
example, the first generation polynomial G1 has non-zero
coefficients at J in order number of $d_{1,1}$ to $d_{1,J}$. Therefore,
15 the outputs of the $(d_{\max} - d_{1,1})$ th to $(d_{\max} - d_{1,J})$ th shift registers
in the syndrome register 221 are fed to the first threshold
value judgment circuit 222-1.

The first to (K)th threshold value judgment circuits 222-1
to 222-K makes judgment that error is caused only when number
20 of signals having value "1" is more than or equal to B among
J in order number of input signals to output "1" as error values
 $E1_1$ to $EK-1$. Here, B is expressed by:

$$B = \lfloor J/2 \rfloor + \alpha \quad \dots\dots (4)$$

09964195-092601

wherein $\lfloor J/2 \rfloor$ is minimum natural number not smaller than $J/2$,
and α is a natural number.

5 When number of the signals having the value "1" is less
than B, judgment is made that error is not caused to output
"0" as the error values $E1_1$ to EK_1 . For example, among the
input signals of the first threshold value judgment circuit
222-1, if B in number of signals have the values "1" exist,
10 judgment is made that error is caused in the delayed first to
(K)th information series $I1_D1$ output from the syndrome series
generation circuit 21 to output "1" as the $E1_1$. The threshold
value B of the threshold value judgment circuit can be set
arbitrary within a range not exceeding J.

15 When error is detected in the threshold value judgment
circuit, error correction performance can be enhanced by
eliminating the influence of the error from the syndrome series
 $S1$. In order to eliminate influence of error from the syndrome
series $S1$, the error values $E1_1$ to EK_1 are fed back to the
20 syndrome register 221. When the fed back error value is one,
the register value of the corresponding shift register is
inverted.

For example when the error value $E1_1$ is "1", the values
of the $(d_{\max} - d_{1,1})$ th to $(d_{\max} - d_{1,J})$ th shift registers in the

09964195-092604

syndrome register 221 are inverted.

Fig. 5 is a block diagram showing a construction of the second decoding circuit 3 of Fig. 1. In Fig. 5, the second decoding circuit 3 is constructed with a syndrome series generation circuit 31, an error value generation circuit 32 and an error correction circuit 33.

It should be noted that the second decoding circuit 3 can be realized by the same construction as the first stage decoding circuit 2 shown in Fig. 2 except that the error detection counter for code synchronization and the check series register for transferring the check series to the next stage decoding circuit are eliminated and the threshold value in the threshold value judgment circuit in the error value generation circuit 32 is different. Operation of the second decoding circuit 3 is the same as that of the first stage decoding circuit 2.

The syndrome series generation circuit 31 generates a syndrome series S2 on the basis of the first stage corrected first to (K)th information series I1_C1 to IK_C1 and the delayed check series PD. The error value generation circuit 32 leads an error value on the basis of the syndrome series S2 input from the syndrome series generation circuit 31.

The error correction circuit 33 corrects the delayed information series I1_D2 to IK_D1 input from the syndrome series generation circuit 31 on the basis of the error values E1_2 to EK_2 input from the error value generation circuit 32 to

09260-5649660

output as second stage first to (K)th corrected information series $I1_C2$ to IK_C2 .

Fig. 6 is a block diagram showing a construction of the syndrome series generation circuit 31 of Fig. 5. In Fig. 6, the syndrome series generation circuit 31 is constructed with first to (K)th information series 311-1 to 311-K, first to (K)th information series exclusive OR circuits 312-1 to 312-K and a syndrome series generation exclusive OR circuit 313.

Each of the first to (K)th information series registers 311-1 to 311-K is constructed with, d_{max} in number of shift registers. The first to (K)th corrected information series $I1_C1$ to IK_C1 are input to the first to (K)th information registers 311-1 to 311-K and then are shifted at every occurrence of clock. The first to (K)th corrected information series $I1_C1$ to IK_C1 delayed for d_{max} clocks are output to the error correction circuit 33 as the first to (K)th delayed information series $I1_D2$ to IK_D2 .

Similarly to the syndrome series generation circuit 21 in the first stage decoding circuit 2, d_{max} in number of shift registers in the first to (K)th information series 311-1 to 311-K correspond to order number of the first to (K)th generation polynomial expression. The signals correspond to the order number the generation polynomial expression having non-zero coefficients are input to the first to (K)th information series exclusive OR circuits 312-1 to 312-K.

09064795-092601

The first to (K)th information series exclusive OR
circuits 312-1 to 312-K take exclusive OR of J in number of
the input signals for outputting the result of exclusive OR
operation to the syndrome series generation exclusive OR circuit
5 313. The syndrome series exclusive OR circuit 313 takes an
exclusive OR of the outputs of the first to (K)th information
series exclusive OR circuits 312-1 to 312-K and the delayed
check series PD to output the result of exclusive OR operation
to the error value generation circuit 32 as the syndrome series
10 S2.

Fig. 7 is a block diagram showing a construction of the
error value generation circuit 32. In fig. 7, the error value
generation circuit 32 is constructed with a syndrome register
321 and first to (K)th threshold value judgment circuits 322-1
15 to 322-K.

The syndrome register 321 is constructed with the d_{\max}
in number of shift registers. The syndrome series S2 are input
to the syndrome register 321 and shifted at every occurrence
of clock. Similarly to the syndrome register 221 in the first
20 stage decoding circuit 2, the d_{\max} in number of shift registers
in the syndrome register 321 corresponds to order number of
the generation polynomial expression. The signals
corresponding to order number of the generation polynomial
expression having non-zero coefficients are output to
25 corresponding threshold value judgment circuit.

05964195 092604
T09260 55149650

The first to (K)th threshold value judgment circuits 322-1 to 322-K makes judgment that error is caused when the signals having value "1" J in number of among input signals is greater than or equal to the threshold value C and outputs "1" as the error values E1_2 to EK_2. Here, the threshold value C of the
5 threshold value judgment is expressed by:

$$C = \lfloor J/2 \rfloor + \beta \quad \dots\dots (5)$$

10 wherein β is natural number.

When number of the signal having the value "1" is less than the threshold value V of the threshold value judgment circuit, judgment is made that error is not caused to output "0" as the error values E1_2 to EK_2. The threshold value C of the threshold
15 value judgment circuit may be set arbitrarily within a range not exceeding J.

For example, comparing the second stage decoding circuit 3 assuming that the threshold value of the threshold value judgment circuit is A set forth above, and the conventional
20 decoding circuit assuming that the threshold value of the threshold value judgment circuit is A, since the signal partly error corrected by the first stage decoding circuit 2 is input to the second stage decoding circuit 3, error correction which could not be corrected in the conventional circuit, can be

09564195-092601
T09260-56T09560

achieved. This number of residual error can be made smaller in comparison with the conventional circuit.

Fig. 8 is a flowchart showing operation of the preferred embodiment of the self orthogonal decoding circuit according to the present invention, and Fig. 9 is a flowchart showing a decoding process by the first stage decoding circuit of Fig. 1. Operation of the shown embodiment of the self orthogonal decoding circuit according to the present invention will be discussed with reference to Figs. 1, 2, 5, 8 and 9.

10 When the reception series U is input to the self orthogonal decoding circuit, the code synchronization and serial/parallel conversion circuit 1 establishes core synchronization and performs serial/parallel conversion of the reception series Y to split into the information series I1 to IK and the check series P to output the first stage decoding circuit 2 (step S1 of Fig. 8).

Here, the code synchronization performs based on the error count value EC input from the first stage decoding circuit 2. For example, when the error count value EC is greater than or equal to the threshold value, judgment is made that code synchronization is broken to vary the phase of the parallel signal to output to the first stage decoding circuit 2.

The first stage decoding circuit 2 takes the information series I1 to IK and the check series P as input and performs error correction on the basis of the information series I1 to

25

09964195-092604
T09260-584966

IK and the check series P to output the first stage corrected first to (K)th information series I1_C1 to IK_C1 and the delayed check series PD to the second stage decoding circuit 3 (step S2 of Fig. 8).

5 Namely, the syndrome series generation circuit 21 of the first stage decoding circuit 2 generates the syndrome series S1 on the basis of the first to (K)th information series I1 to IK input from the code synchronization and serial/parallel conversion circuit 1 and the check series P (step S11 of Fig. 9) and stores the generated syndrome series S1 (step S12 of Fig. 9). The error value generation circuit 22 performs error judgment on the basis of the syndrome series S1 input from the syndrome series generation circuit 21 (step S13 of Fig. 9) for leading the error value.

10 The error detection counter 24 takes the error value E1_1 to EK_1 as inputs to count the error count detected over a given period to output the result of count as error count value EC to the code synchronization and serial/parallel conversion circuit 1 (step S17 of Fig. 9).

15 The error correction circuit 23 corrects the delayed information series I1_D1 to IK_D1 input from the syndrome series generation circuit 21 on the basis of the error value E1_1 to EK_1 input from the error value generation circuit 22 (step S14 of Fig. 9) to output the first stage corrected first to (K)th information series I1_C1 to IK_C1 to the second stage

20

25

0906495 092604
T09260 554969

decoding circuit 3 (step S15 of Fig. 9).

Assuming that the maximum value of the maximum order number $d_{1,j}$ to $d_{K,j}$ of the first to (K)th generation polynomial expression G1 to GK is d_{\max} , the check series register 25 shifts the check series P at every occurrence of clock to output the check series P delayed for d_{\max} in number of clocks to the second stage decoding circuit 3 as the delayed check series PD (step S16 of Fig. 9).

Subsequently, the second stage decoding circuit 3 performs similar process as the decoding process by the first stage decoding circuit 2 (step S3 of Fig. 8) and performs error correction for the first stage corrected first to (K)th information series I1_C1 to IK_C1 reduced number of error by the first stage decoding circuit 2 to further reduce number of error.

Namely, the syndrome series generation circuit 31 of the second stage decoding circuit 3 generates a syndrome series S2 on the basis of the first stage corrected first to (K)th information series I1_C1 to IK_C1 input from the first stage decoding circuit 2 and the delayed check series PD. The error value generation circuit 32 lead an error value on the basis of the syndrome series S2 input from the syndrome series generation circuit 31.

The error correction circuit 33 performs correction of the delayed information series I1_D2 to IK_D2 input from the syndrome series generation circuit 31 on the basis of the error

09564195-092604
T09260-5049560

value E1_2 to EK_2 input from the error value generation circuit 32 to output as second stage corrected first to (K)th information series I1_C2 to IK_C2.

As set forth above, the shown embodiment of the self
5 orthogonal decoding circuit repeats decoding process by first stage to (N)th stage decoding circuits (in Fig. 3, the third stage to (N)th stage decoding circuits are eliminated from illustration) (steps S4 to SB+1 of Fig. 8) for improving error correction performance for gradually reducing number of error.

10 Particularly, by setting the threshold value of the threshold value judgment circuit in the first decoding large to make correction only for highly probable errors, and in the subsequent stages, the threshold values of the threshold value judgment circuits are gradually reduced in accordance with
15 progress of decoding to correct errors of lower probability. This manner of error correction reduces possibility of causing erroneous correction to significantly improve error correction performance. The decoding process in the second decoding circuit to the (N)th decoding circuit is similar to the decoding
20 process in the first stage decoding circuit 2.

When error is detected in the threshold value judgment circuit, by removing influence of error from the syndrome series, error correction performance can be improved. In order to eliminate influence of error from the syndrome series, the error
25 value E1_2 to EK_2 are fed back to the syndrome register 321.

0954195-092604

When the fed back error value is "1", the value of the corresponding shift register is inverted.

In the shown embodiment of the decoding circuit according to the present invention as set forth above, discussion has
5 been given for the case where decoding is repeated twice. However, as shown in Fig. 8, number times of decoding can be set arbitrarily and thus should not be specified to two as in the shown embodiment.

Fig. 10 is a block diagram showing an example of
10 construction of a system employing the preferred embodiment of the self-orthogonal decoding circuit according to the present invention. In Fig. 10, the shown system is constructed with a self orthogonal decoding circuit 11 of the construction and operation as set forth above, an information source 12 generating
15 the information series, an encoder 13 converting the information series generated in the information source 12 into a code series, and a communication path 14 transmitting the code series converted by the encoder 13 to the self orthogonal decoding circuit 11.

20 Namely, as set forth above, the self orthogonal decoding circuit 11 is constructed with the code synchronization and serial/parallel conversion circuit 1, the first stage decoding circuit 2 and the second stage decoding circuit 3 and is responsive to reception of the code series converted by the encoder 13
25 as the reception series to perform decoding process (code

09964195-092601

synchronization, error correction and so forth) by the foregoing process operation.

It should be noted that the information source 12 may be storage medium, such as CD (Compact Disk), DVD (Digital Versatile Disk), hard disk or the like, information processing equipment generating information, generation circuit generating an audio signal or the like. On the other hand, as communication line, radio communication, wired communication by a wired cable, an optical cable or the like. However, the information source 12 and the communication path 14 are not specified to those listed above.

Fig. 11 is a block diagram showing an example of a construction of a radio system employing the preferred embodiment of the self-orthogonal decoding circuit according to the present invention. In Fig. 11, the shown radio system is constructed with the self orthogonal decoding circuit 11 taking the construction and operation set forth above, the information source 12 generating the information series, the encoder 13 converting the information series generating by the information source 12 into the code series, and a radio transmitter 15 and a radio receiver 16 for radio transmission of the code series converted by the encoder 13 to the self orthogonal decoding circuit 11.

Namely, as set forth above, the self orthogonal decoding circuit 11 is constructed with the code synchronization and

09964195.002601

serial/parallel conversion circuit 1, the first stage decoding circuit 2 and the second stage decoding circuit 3. The self orthogonal decoding circuit 11 is responsive to the code series generated by the encoder 13 transmitted and received through the radio transmitter 15 and the radio receiver 16 as the reception series to perform the foregoing process operation for decoding process (code synchronization, error correction and so forth). The self orthogonal decoding circuit 11 is similar to a general purpose system except for the decoding process set forth above.

10 Fig. 12 is a block diagram showing an example of a construction of a transmission system of an optical cable employing the preferred embodiment of the self-orthogonal decoding circuit according to the present invention. In Fig. 12, an optical cable transmission system is constructed with 15 transmission stations 17 and 19 and receiving stations 18 and 20. It should be noted that the transmission stations 17 and 19 and the receiving stations 18 and 20 are located on the ground. Between the transmission station 17 and the receiving station 18 and between the transmission station 19 and the receiving station 20 are connected by submarine optical cables 201 and 202.

25 An optical signal transmitted from the transmission station 17 is transmitted to the receiving station 18 through the submarine optical cable 201. In the receiving station 18, the optical signal is converted into a digital signal (electric

09464195-092601

signal). Then, the digital signal thus converted is subject to decoding process, such as code synchronization, error correction and so forth and then transferred to the transmission station 19. The transmission station 19 converted the signal
5 provided the decoding process by the receiving station 18 into the optical signal to transmit to the receiving station 20 via the submarine optical cable 201. The receiving station 20 converts the optical signal from the transmission station 19 into the digital signal (electrical signal) to perform decoding
10 process, such as code synchronization, error correction or the like.

Fig. 13 is a block diagram showing a construction of a receiving station of Fig. 12. In Fig. 13, the receiving station 18 is constructed with the self orthogonal decoding circuit
15 11 taking construction and operation set forth above, an optical splitter 181 and an photoelectric transducer 182. The optical splitter 181 separates the optical signal input through the submarine optical cable 201. The photoelectric transducer 182 converts the separated optical signal into the electric signal
20 (digital signal).

As set forth above, the self orthogonal decoding circuit 11 is constructed with the code synchronization and serial/parallel conversion circuit 1, the first stage decoding circuit 2 and second stage decoding circuit 3. The self
25 orthogonal decoding circuit 11 is responsive to the electric

0954195-092601

signal converted by the photoelectric transducer 182 as the reception series to perform the process set forth above for decoding process (code synchronization, error correction or the like). It should be noted that the receiving station 20
5 has the same construction and operation as those in the receiving station 18.

Fig. 14 is a block diagram showing a construction of another embodiment of the self orthogonal decoding circuit according to the present invention. In Fig. 14, another embodiment of
10 the self orthogonal decoding circuit according to the present invention is constructed with a code synchronization and serial/parallel conversion circuit 4, a first stage decoding circuit 5 and a second stage decoding circuit 6. It should be noted that, Fig. 14, there is shown a circuit construction in
15 the case where the coding ratio is $1/2$, the code generation polynomial expression is the foregoing expression (1), and number of times of repetition of decoding is two.

The code synchronization and serial/parallel conversion circuit 4 takes the reception series Y and the error count value
20 EC output from the first stage decoding circuit 5 as input to perform code synchronization on the base of the error count value EC. The circuit 4 performs serial/parallel conversion for the reception series Y to output the information series I and the check series P to the first stage decoding circuit
25 5.

09564195-092601
T09260-55419560

The first stage decoding circuit 5 receives the input of the information series I and the check series P to perform error correction on the basis of the information series I and the check series P to output a first stage corrected information series IC1 and the delayed check series PD to the second stage decoding circuit 6.

The second stage decoding circuit 6 takes the first stage corrected information series IC1 and the delayed check series PD to perform error correction on the basis of the first stage corrected information series IC1 and the delayed check series PD to output the second stage corrected information series IC2.

Fig. 15 is a block diagram showing a construction of the first stage decoding circuit 5 of Fig. 14. In Fig. 15, the first stage decoding circuit 5 is constructed with a syndrome series generation circuit 51, an error value generation circuit 52 and an error correction circuit 53.

The syndrome series generation circuit 51 generates the syndrome series S1 on the basis of the information series I input from the code synchronization and serial/parallel conversion circuit 4 and the check series P. The error value generation circuit 52 leads the error value on the basis of the syndrome series S1 input from the syndrome series generation circuit 51.

The error correction circuit 53 corrects the detailed information series ID1 input from the syndrome series generation

09564195-092601
T09260-5674960

circuit 51 on the basis of the error value E1 input from the error value generation circuit 52 to output to the second stage decoding circuit 6 as the first stage corrected information series IC1.

5 Fig. 16 is a block diagram showing a construction of the syndrome series generation circuit 51 of Fig. 15. In Fig. 16, the syndrome series generation circuit 51 is constructed with first to sixth information series registers 511-1 to 511-6, an exclusive OR circuit 512 and first to sixth check series
10 registers 513-1 to 513-6.

 The first information series register 511-1 takes the information series I as input to output one clock delayed signal to the second information series register 511-2. The second information series register 511-2 takes the output of the first
15 information register 511-1 as input to output one clock delayed signal to the third information series register 511-3. Similarly, the third to sixth information series registers 511-3 to 511-6 are connected in series. The sixth information series register 511-6 outputs the delayed information series ID1
20 delayed for six clocks relative to the information series I to the error correction circuit 53.

 The exclusive OR circuit 512 takes the information series I, the outputs of the second, fifth and sixth information series registers and the check series P as inputs and outputs the result
25 of exclusive OR operation to the error value generation circuit

09260155-092601

52 as the syndrome series S1. The information series I, the second, fifth and sixth information series registers correspond to order number 0, 2, 5 and 6 of generation polynomial expression having non-zero coefficients.

5 The first check series register 513-1 takes the check series P as input to output the signal delayed for one clock to the second check series register 513-2. Similarly, the second to sixth check series registers 513-2 to 513-6 are also connected in series. The sixth check series register 513-6 outputs the
10 delayed check series PD delayed for six clocks relative to the check series P to the second stage decoding circuit 6.

Fig. 17 is a block diagram showing a construction of the error value generation circuit 52 of Fig. 15. In Fig. 17, the error value generation circuit 52 is constructed with zeroth
15 to fifth syndrome registers 521-0 to 521-5, a threshold value judgment circuit 523, a error detection counter 524 and syndrome correcting exclusive OR circuits 522-1 to 522-3.

The threshold value judgment circuit 523 takes the syndrome series S1 and outputs of the fifth, second and zeroth
20 syndrome registers as inputs. When number of input signals having value "1" is greater than or equal to the threshold value, judgment is made that error is caused to output "1" as the error value E1 to the syndrome correcting exclusive OR circuits 522-1 to 522-3, the error detection counter 524 and error correction
25 circuit 53, respectively.

0954195-092601
109260-5679650

When the number of input signals having value "1" is less than the threshold value, judgment is made that error is not caused, to output zero as the error value E1. The syndrome series S1 and the fifth, second and zeroth syndrome registers
5 respectively correspond to order number 6, 5, 2, 0 of the generation polynomial expression having non-zero coefficients.

The zeroth to fifth syndrome registers 521-0 to 521-5 and the syndrome correcting exclusive OR circuits 522-1 to 522-3 have function for shifting from higher order register to lower
10 order register at every occurrence of clock. Furthermore, in order to eliminate influence of error from the syndrome series, the signal output to the threshold value judgment circuit 523 has a function for inverting the value. In order to realize this function, the zeroth to fifth syndrome registers 521-0
15 to 521-5 and the syndrome correcting exclusive OR circuits 522-1 to 522-3 are connected in the following manner.

The syndrome correcting exclusive OR circuit 522-1 takes the syndrome series S1 and the error value E1 as inputs and outputs the result of exclusive OR operation to the fifth syndrome
20 register 521-5. The fifth syndrome register 521-5 takes the output of the syndrome correcting exclusive OR circuit 522-1 as input to output one clock delayed signal to the syndrome correcting exclusive OR circuit 522-2 and the threshold value judgment circuit 523.

25 The syndrome correcting exclusive OR circuit 522-2 takes

09064195-092601

the output of the fifth syndrome register 521-5 and the error value E1 to output the result of exclusive OR operation to the fourth syndrome register 521-4. The fourth syndrome register 521-4 takes the output of the syndrome correcting exclusive OR circuit 522-2 as input to output one clock delayed signal to the third syndrome register 521-3.

The third syndrome register 521-3 takes the output of the fourth syndrome register 521-4 as input, and outputs one clock delayed signal to the second syndrome register 521-2. The second syndrome register 521-2 takes the output of the third syndrome register 521-3 as input to output the one clock delayed signal to the syndrome correcting exclusive OR circuit 522-3 and the threshold value judgment circuit 523.

The syndrome correcting exclusive OR circuit 522-3 takes the output of the second syndrome register 521-2 and the error value E1 as input to output the result of exclusive OR operation to the first syndrome register 521-1. The first syndrome register 521-1 takes the output of the syndrome correcting exclusive OR circuit 522-3 as input to output the one clock delayed signal to the zeroth syndrome register 521-0. The zeroth syndrome register 521-0 takes the output of the first syndrome register 521-1 as input to output the one clock delayed signal to the threshold value judgment circuit 523.

The error detection counter 524 takes the error value E1 as input to count the number of errors detected within a

0964195-092604

given period. The counted error count value EC is output to the code synchronization and serial/parallel conversion circuit 4. When transmission path condition is quite bad and number of inserted error is large, error correction is caused at every time of repetition of decoding number of errors to be detected upon in code synchronized condition and in asynchronous condition. Therefore, in the shown embodiment, error detection counter 524 is provided in the first stage decoding circuit 2. It should be noted that the error detection counter is not necessarily required to be provided in the first stage decoding circuit but can be provided in any stage of decoding circuit.

Fig. 18 is a block diagram showing a construction of the second decoding circuit 6 of Fig. 14. In Fig. 18, the second stage decoding circuit 6 is constructed with a syndrome series generation circuit 61, a error value generation circuit 62 and a error correction circuit 63. The second stage decoding circuit 6 can be realized with the same construction as the first stage decoding circuit 5 shown in Fig. 15 except that the error detection counter for code synchronization and the check series register for transferring the check series to the decoding circuit in the next stage are eliminated.

The syndrome series generation circuit 61 generates the syndrome series S2 on the basis of the first stage corrected information series IC1 input from the first stage decoding circuit 5 and the delayed check series PD. The error value

09464195-092604

generation circuit 62 leads the error value on the basis of the syndrome series S2 input from the syndrome series generation circuit 61.

The error correction circuit 63 corrects delayed
5 information series ID2 input from the syndrome series generation circuit 61 on the basis of the correction value E2 input from the error value generation circuit 62 to output it as the second stage corrected information series IC2.

Fig. 19 is a block diagram showing a construction of the
10 syndrome series generation circuit 61 of Fig. 18. In Fig. 19, the syndrome series generation circuit 61 is constructed with first to sixth information series registers 611-1 to 611-6 and an exclusive OR circuit 612.

The first information series register 611-1 takes the
15 first stage corrected information series IC1 as input and outputs a signal delayed for one clock to the second information series register 611-2. The second information series register 611-2 takes the output of the first information series register 611-1 as input and outputs a signal delayed for one clock to the third
20 information series register 611-3. Similarly, the third to sixth information series registers 611-3 to 611-6 are also connected in series. The sixth information series register 611-6 outputs the delayed information series ID2 delayed for six clocks relative to the first stage corrected information
25 series IC1 to the error correction circuit 63.

09964195-092601
T09260-56T9660

The exclusive OR circuit 612 takes the first stage corrected information series IC1, the outputs of the second, fifth and sixth information series registers and the delayed check series PD as inputs and outputs the result of exclusive OR operation to the error value generation circuit 62 as syndrome series S2. The first stage corrected information series IC1, the second, fifth and sixth information series register respectively correspond to order numbers of 0, 2, 5 and 6 of the generation polynomial having coefficients other than zero.

Fig. 20 is a block diagram showing a construction of the error value generation circuit 62 of Fig. 18. In Fig. 20, the error value generation circuit 62 is constructed with zeroth to fifth syndrome registers 621-0 to 621-5, a threshold value judgment circuit 623 and syndrome correcting exclusive OR circuits 622-1 to 622-3.

The threshold value judgment circuit 623 takes the syndrome series S2 and the outputs of the fifth, second and zeroth syndrome registers as input to make judgment that error is caused when number of input signals having value "1" is greater than the threshold value to output "1" to the syndrome correcting exclusive OR circuits 622-1 to 622-3 and the threshold value judgment circuit 623 as the correction value E2.

When number of the input signals having value "1" is less than the threshold value, judgment is made that error is not caused to output "0" as the error value E2. The syndrome series

09564195-092604
T09260-564195

S2, the fifth, second and zeroth information series syndrome register respectively correspond to order numbers of 6, 5, 2, 0 of the generation polynomial having coefficients other than zero.

5 The zeroth to fifth syndrome registers 621-0 to 621-5 and the syndrome correcting exclusive OR circuits 622-1 to 622-3 have function for shifting the syndrome series S2 from higher order register to lower order register at every occurrence of clock. Furthermore, in order to eliminate influence of error
10 from the syndrome series S2, the signal output to the threshold value judgment circuit 623 has a function for inverting the value when the error is detected. In order to realize the foregoing function, the zeroth to fifth syndrome registers 621-0 to 621-5 and the syndrome correcting exclusive OR circuits 622-1
15 to 622-3 are connected in the following manner.

 The syndrome correcting exclusive OR circuit 622-1 takes the syndrome series S2 and the correction value E2 as inputs and outputs the result of exclusive OR operation to the fifth syndrome register 621-5. The fifth syndrome register 621-5
20 takes the output of the syndrome correcting exclusive OR circuit 622-1 as input to output one clock delayed signal to the syndrome correcting exclusive OR circuit 622-2 and the threshold value judgment circuit 623.

 The syndrome correcting exclusive OR circuit 622-2 takes
25 the output of the fifth syndrome register 621-5 and the correction

09964195-092501

value E2 as input and outputs the result of exclusive OR operation to the fourth syndrome register 621-4. The fourth syndrome register 621-4 takes the output of the syndrome correcting exclusive OR circuit 622-2 as input to output the one clock
5 delayed signal to the third syndrome register 621-3.

The third syndrome register 621-3 takes the output of the fourth syndrome register 621-4 as input to output the one clock delayed signal to the second syndrome register 621-2. The second syndrome register 621-2 takes the output of the third
10 syndrome register 621-3 as input to output one clock delayed signal to the syndrome correcting exclusive OR circuit 622-3 and the threshold value judgment circuit 623.

The syndrome correcting exclusive OR circuit 622-3 takes the output of the second syndrome register 621-2 and the
15 correction value E2 as input to output the result of exclusive OR operation to the first syndrome register 621-1. The first syndrome register 621-1 takes the output of the syndrome correcting exclusive OR circuit 622-3 as input to output one clock delayed signal to the zeroth syndrome register 621-0.
20 The zeroth syndrome register 621-0 takes the output of the first syndrome register 621-1 as input to output one clock delayed signal to the threshold value judgment circuit 623.

Next, in the shown embodiment of the self-orthogonal decoding circuit according to the present invention, operation
25 will be discussed with reference to Figs. 14 to 20 and in terms

09260105-092601

that the coding ratio is $1/2$, the code generating polynomial expression is foregoing (1), number of orthogonal is four and number or times of repetition of decoding is 2.

In case of the self orthogonal code of coding ratio $1/2$,
5 the check series of the same ratio is added to the information series in the not shown encoder to generate a transmission series, in which the information series and check series are arranged alternately. The transmission series is output to the line and the reception series Y, which is generated by adding error to
10 the transmission system, is input to the decoding circuit.

The code synchronization and serial/parallel conversion circuit 4 performs code synchronization, serial/parallel conversion of the reception series Y to output the information series I and the check series P to the first stage decoding
15 circuit 5. At this time, the code synchronization in the code synchronization and serial/parallel conversion circuit 4 is performed on the basis of error count value EC input from the first stage decoding circuit 5. For example, when the error count value EC is greater than or equal to the threshold value,
20 judgment is made that code synchronization is broken to vary phase of the parallel signal to be output to the first stage decoding circuit 5.

The first stage decoding circuit 5 takes the information series I and the check series P as inputs to perform error
25 correction on the basis of the information series I and the

0964195.092601
T09260.964195

check series P for outputting the first stage corrected information series IC1 and the delayed check series PD to the second stage decoding circuit 6.

The information series I is input to the first information series register 511-1 and is shifted to higher order information series register at every occurrence of the clock. Accordingly, the delayed information series ID1 output from the sixth information series register 511-6 is delayed for six clocks relative to the information series I. The delayed information series ID1 delayed by the information series register is output to the error correction circuit 53.

Order number of the information series register corresponds to order number of generation polynomial expression. The input information series I correspond to zeroth of generation polynomial expression. The syndrome series S1 derived by exclusive OR of the signal corresponding to order number of the generation polynomial expression having non-zero coefficient and the check series P.

The generation polynomial expression of the shown embodiment has non-zero coefficient at zeroth, second, fifth and sixth order. Therefore, the information series I, the outputs of the second, fifth and sixth information series registers and the check series P are input to the exclusive OR circuit 512. The exclusive OR circuit 512 takes an exclusive OR of the input signals to output the result to the error value

09964195-092601

generation circuit 52 as the syndrome series S1.

The check series P is input to the first check series register 513-1 and is shifted to higher order check series register at every occurrence of clock. Accordingly, the delayed check series PD output from the sixth check series register 513-6 is delayed for six clocks relative to the check series P. The delayed check series PD delayed in the same extent as the information series is output to the second stage decoding circuit 6.

10 The error value generation circuit 52 leads an error value on the basis of the syndrome series S1 input from the syndrome series generation circuit 51. The syndrome series S1 is input to the fifth syndrome register 521-5 and then shifted to lower order syndrome register at every occurrence of the clock. Number
15 of orders of the syndrome registers corresponds to order number of the generation polynomial expression. The syndrome series S1 corresponds to sixth order.

The signal corresponding to order number of the generation polynomial expression having non-zero coefficient is output
20 to the threshold value judgment circuit 523. In the shown embodiment, the syndrome series S1 and the outputs of the fifth, second and zeroth syndrome registers are output to the threshold value judgment circuit 523.

For example, consideration is given that the case where
25 the threshold value of the threshold value judgment circuit

0964195-092601

523 is four. In this case, when all of the input signals of the four threshold value judgment circuits are "1", judgment is made that error is contained in the delayed information series ID1 to output as the error value E1. When number of input signals
5 having value "1" is less than four, judgment is made that error is not contained in the delayed information series ID1 to output "0" as the error value E1.

When error is detected in the threshold value judgment circuit 523, in order to eliminate influence of error from the syndrome series S1, the signal input to the threshold value
10 judgment circuit 523 inverts the value when the error is detected and input to the lower order syndrome register. Particularly, inversion of the value is performed by the syndrome correcting exclusive OR circuits 522-1 to 522-3.

15 The syndrome correcting exclusive OR circuits 522-1 to 522-3 takes the syndrome series S1 and outputs of the fifth and second syndrome registers as first input and the error value E1 as second input. The syndrome correcting exclusive OR circuits 522-1 to 522-3 takes an exclusive OR of the first input
20 and the second input to output the result of exclusive OR operation to respective of the fifth, fourth and first syndrome registers.

The error detection counter 524 receives the error value E1 as input to count number of errors detected with a given period. The error count value EC as counted is output to the
25 code synchronization and serial/parallel conversion circuit

09964195-092601

4.

The error correction circuit 53 corrects the delayed information series ID1 input from the syndrome series generation circuit 51 on the basis of the error value E1 input from the error value generation circuit 52 to output the first stage corrected information series IC1 to the second stage decoding circuit 6. The second stage decoding circuit 6 performs error correction for the first stage corrected information series IC1 reduced number of error in the first stage decoding circuit 5 to further reduce number of errors.

The first to sixth information series registers 611-1 to 611-6 has a function for delaying the information series until end of the error detection process and a function for generating syndrome series S2 together with the exclusive OR circuit 612.

The delayed information series ID1 is input to the first information series register 611-1 and is shifted to higher order information series register at every occurrence of clock to output the delayed information series ID2 delayed by the information series register to the error correction circuit 63.

The order number of the information series register corresponds to the order number of generation polynomial expression. The delayed information series ID1 corresponds to zeroth of the generation polynomial expression. The syndrome

09064195-092601

series S2 is derived by exclusive OR of the signal corresponding to order number of the generation polynomial expression having non-zero coefficients and the delayed check series PD.

The generation polynomial expression in the shown embodiment has non-zero coefficients at zeroth, second, fifth and sixth order. Therefore, the delayed information series ID1, the outputs of the second, fifth and sixth information series registers and the delayed check series PD are input to the exclusive OR circuit 612. The exclusive OR circuit 612 takes exclusive OR of the input signals to output the result of the exclusive OR operation to the error value generation circuit 62 as the syndrome series S2.

The error value generation circuit 62 leads the error value on the basis of the syndrome series S2 input from the syndrome series generation circuit 61. The syndrome series S2 is input to the fifth syndrome register 621-5 to be shifted to lower order syndrome register at every occurrence of clock. The order number of the syndrome register corresponds to order number of generation polynomial expression. The syndrome series S2 corresponds to sixth order.

The signal corresponding to order number of the generation polynomial expression having non-zero coefficient is output to the threshold value judgment circuit 623. In the shown embodiment, the syndrome series S2 and the outputs of the fifth, second and zeroth syndrome registers are output to the threshold

09964195-092601

value judgment circuit 623.

For example, consideration is given for the case where the threshold value judgment circuit 623 is three. In this case, when number of input signals having value "1" is greater than
5 or equal to 3, judgment is made that error is caused to output "1" as correction value E2. If the number of input signal having value "1" is less than 3, judgment is made that error is not contained to output "0" as correction value E2.

The conventional decoding circuit performs decoding of
10 the threshold value 3 only once in the threshold value judgment circuit. The shown embodiment of the decoding circuit performs decoding for a plurality of times to improve error correction performance. In the shown embodiment, the threshold value of the threshold value judgment circuit of the first stage decoding
15 circuit 5 is set at 4 and the threshold value of the threshold value judgment circuit of the second stage decoding circuit 6 is set at 3. In this case, only those having high probability of containing error are corrected in the first stage decoding circuit 5.

20 The threshold value of the threshold value judgment circuit of the second stage decoding circuit 6 is the same as the conventional decoding circuit. However, since the signal, in which part of the error is corrected in the first stage decoding circuit 5 is input, possibility of occurrence of error correction
25 can be reduced, and error which could not be corrected by the

09064195-092604
109260-5674960

conventional decoding circuit can be corrected. Therefore, the output of the second stage decoding circuit 6 has smaller number of residual error in comparison with the output of the conventional decoding circuit.

5 When error is detected by the threshold value judgment circuit 623, error correction performance can be enhanced by eliminating influence of error from the syndrome series S2. In order to eliminate the influence of error from the syndrome series S2, the signal to be input to the threshold value judgment
10 circuit 623 is inverted the value thereof when error is detected and then input to the lower order syndrome register. Particularly, inversion of the values is performed by the syndrome correcting exclusive OR circuits 622-1 to 622-3.

 The syndrome correcting exclusive OR circuits 622-1 to
15 622-3 take the syndrome series S2, the outputs of the fifth and second syndrome registers as first input and the correction value E2 as second input. The syndrome correcting exclusive OR circuits 622-1 to 622-3 take exclusive OR of the first and second inputs to output the result of exclusive OR operation
20 to the fifth, fourth and first syndrome registers.

 The error correction circuit 63 corrects the delayed information series ID2 input from the syndrome series generation circuit 61 on the basis of the correction value E2 input from the error value generation circuit 62 to output as second stage
25 corrected information series IC2.

09564195-092601

Next, in the shown embodiment of the self-orthogonal decoding circuit according to the present invention, operation has been discussed in terms that the coding ratio is $1/2$, the code generating polynomial expression is foregoing (1), number
5 of orthogonal is four and number of times of repetition of decoding is 2. However, coding ratio, number of orthogonal, generation polynomial expression and number of times of repetition of decoding can be set arbitrary.

The conventional decoding had encountered problem in low
10 error correction performance while decoding is easily and can be easily applied for systems. The present invention can be realized with simple circuit construction and can achieve significantly high error correction performance.

By delaying the check series using the check series
15 register and inputting the result of the delaying to the next decoding circuit, decoding can be repeated and the error correction performance can be significantly improved.

On the other hand, by setting the threshold value of the threshold value judgment circuit in the first decoding large
20 to make correction only for highly probable errors, and in the subsequent stages, the threshold values of the threshold value judgment circuits are gradually reduced in accordance with progress of decoding to correct errors of lower probability. This manner of error correction reduces possibility of causing
25 erroneous correction to significantly improve error correction

09964195-092601

performance.

Next, another embodiment of the present invention will be discussed with reference to the drawings. In one embodiment of the present invention, the error value output from the threshold value judgment circuit in the first stage decoding circuit is counted to perform judgment of code synchronization on the basis of the counted error detection number. However, the threshold values of the threshold value judgment circuit in the first stage decoding circuit are set large, number of error detection upon code synchronization and number of error detection in asynchronous state are not significantly different to cause difficulty in judgment of code synchronization/asynchronization.

In order to solve this problem, in another embodiment of the present invention, separately from the threshold value judgment circuit for error generation, the threshold value judgment circuit dedicated for code synchronization is provided for setting the threshold value low. Hereinafter, similarly to one embodiment of the present invention, operation and construction of another embodiment of the present invention will be discussed in terms that the coding ratio is $1/2$, the code generating polynomial expression is foregoing (1), number of orthogonal is four and number of times of repetition of decoding is 2.

Another embodiment of the decoding circuit according to

099260" 55T49560

the present invention has similar construction as one embodiment of the present invention except for providing of the threshold value judgment circuit dedicated for code synchronization in the error generation circuit 52 in the first stage decoding circuit 5 and threshold value is set at lower value. In the following discussion, the same reference numerals as the former embodiment of the present invention will be used.

Fig. 21 is a block diagram showing a construction of an error value generation circuit in another embodiment of the first stage decoding circuit according to the present invention. In Fig. 21, the error value generation circuit 52 in another embodiment of the present invention, is constructed with the zeroth to fifth syndrome registers 521-0 to 521-5, the threshold value judgment circuit 523, the error detection counter 524, the syndrome correcting exclusive OR circuits 522-1 to 522-3 and code synchronization dedicated threshold value judgment circuit 525.

Fig. 22 is a flowchart showing decoding process in another embodiment of the first stage decoding circuit according to the present invention. Decoding process in the first stage decoding circuit in another embodiment of the present invention will be discussed with reference to Figs. 21 and 22. Process operation at steps 21 to 26 are similar to the process operation at steps 11 to 16 shown in Fig. 9. Discussion for these process operation will be eliminated.

09564195-092601

The signal corresponding to order number of the generation polynomial expression having non-zero coefficients is output to the code synchronization dedicated threshold value judgment circuit 525. In the shown embodiment, the outputs of the syndrome series S1 and the fifth, second and zeroth syndrome registers are output to the code synchronization dedicated threshold value judgment circuit 525.

The code synchronization dedicated threshold value judgment circuit 525 makes judgment that error is caused when number of signals having value "1" is greater than the threshold value, to output "1" as the error value ES. When number of signals having value "1" is less than the threshold value, judgment is made that error is not caused to output "0" as the error value ES.

The error value ES is output to the error detection counter 524 to count number of errors detected within the given period. The counted error count value EC is output to the code synchronization and serial/parallel conversion circuit 4 (step S28 of Fig. 22).

In another embodiment of the present invention, the threshold value of the code synchronization dedicated threshold value judgment circuit 525 is 3 and the threshold value of the threshold value judgment circuit 523 is 4, for example, in comparison with the method counting the error number on the basis of the error value E1 output by the threshold value judgment

0996495-092601

circuit 523, erroneous judgment of code synchronization and asynchronization can be reduced.

Subsequently, a further embodiment of the present invention will be discussed with reference to the drawings.

5 In one embodiment of the present invention, the error value output from the threshold value judgment circuit in the first stage decoding circuit is fed back to correct syndrome series. Particularly, when error of the threshold value judgment circuit is detected, a process for inverting the syndrome series input
10 to the threshold value judgment circuit is performed.

However, by performing inversion process of the syndrome series, number of registers storing "1" in the syndrome register can be reduced even when the code synchronization is not established. When number of registers in the syndrome register
15 storing "1" is reduced, occurrence of judgment of error by the threshold value judgment circuit can be reduced to cause difficulty in discrimination of synchronized state and asynchronized state.

Therefore, in another embodiment of the present invention,
20 in addition to the error value generating syndrome register and the threshold value judgment circuit, the syndrome register and the threshold value judgment circuit dedicated for code synchronization are provided to so as not to perform correction on the basis of the result of error judgment by the code
25 synchronizing syndrome register.

09964195-092604
109260-5649660

Similarly to one embodiment of the present invention, operation and construction of another embodiment of the present invention will be discussed in terms that the coding ratio is $1/2$, the code generating polynomial expression is foregoing
5 (1), number of orthogonal is four and number of times of repetition of decoding is 2.

Another embodiment of the decoding circuit according to the present invention has similar construction as one embodiment of the present invention except that the syndrome register and
10 the threshold value judgment circuit dedicated for code synchronization is provided in the error value generation circuit 52 in the first stage decoding circuit 5, and a method not to perform correction on the basis of the result of error judgment in the code synchronizing syndrome register. In the
15 following discussion, the reference numerals similar to one embodiment of the present invention are used.

Fig. 23 is a block diagram showing a construction of the error value generation circuit in a further embodiment of the first stage decoding circuit according to the present invention.
20 In Fig. 23, the error value generation circuit 52 in another embodiment of the present invention is constructed with zeroth to fifth syndrome registers 521-0 to 521-5, the threshold value judgment circuit 523, the error detection counter 524, code synchronization dedicated threshold value judgement circuit
25 525, the zeroth to fifth code synchronization dedicated syndrome

09964195-092601

registers 526-0 to 526-5.

Fig. 24 is a flowchart showing a decoding process in a further embodiment of the first stage decoding circuit according to the present invention. Decoding process in the first decoding circuit in another embodiment of the present invention will be discussed with reference to Figs. 23 and 24. It should be noted that, in Fig. 24, process operation in steps 31 to 36 is similar to the process operation of steps 11 to 16 shown in Fig. 9. Therefore, discussion for the process operation will be eliminated from disclosure.

The syndrome series S2 is input to the fifth code synchronizing syndrome register 526-5 to shift to lower order syndrome register at every occurrence of clock (step S37 of Fig. 24). Order number of syndrome register corresponds to order number of generation polynomial expression. The syndrome series S2 corresponds to sixth order.

The signals corresponding to order number of the generation polynomial expression having non-zero coefficients output to the code synchronization dedicated threshold value judgment circuit 525. In case of the shown embodiment, the syndrome series S1 and outputs of the fifth, second and zeroth code synchronization dedicated syndrome registers are output to the code synchronization dedicated threshold value judgment circuit 525. The code synchronization dedicated threshold value judgment circuit 525 makes judgment that error is caused

0964195-092601

when the number of signals having value "1" is greater than or equal to the threshold value to output "1" as error value ES. When the number of signals having value "1" is less than the threshold value, judgment that error is not caused, is made
5 to output "0" as the error value ES (step S38 of Fig. 24).

The error value ES is output to the error detection counter 524 to count the error number detected within the given period. The error count value EC thus counted is output to the code synchronization and serial/parallel conversion circuit 4 (step
10 S39 of Fig. 24). The syndrome series input to the code synchronization dedicated threshold value judgment circuit 525 is not corrected on the basis of result of error judgment to make erroneous judgment of code synchronization and asynchronization small.

15 As set forth above, according to the present invention, some of the syndrome bits determined by only error of the reception series is output in the self orthogonal decoding circuit performing decoding for the self orthogonal code as convolution code to have parity check sum orthogonal to information bit
20 of the block at a timing 0, decoding for self orthogonal code is repeated for a plurality of times to realize self orthogonal decoding with simple circuit construction to significantly improve error correction performance.

Although the present invention has been illustrated and
25 described with respect to exemplary embodiment thereof, it

09064195-092601

should be understood by those skilled in the art that the foregoing and various other changes, omission and additions may be made therein and thereto, without departing from the spirit and scope of the present invention. Therefore, the present invention
5 should not be understood as limited to the specific embodiment set out above but to include all possible embodiments which can be embodied within a scope encompassed and equivalent thereof with respect to the feature set out in the appended claims.

09964195-092601
